

Functions

What is function?

- Piece of code to accomplish certain operation.
- It has a name for identification
- They are of two types
 - Predefined functions
 - User defined functions

```
#include<stdio.h>
```

FUNCTION SYNTAX

```
void abc(); //function prototype declaration
```

```
void main()  
{  
    abc(); //function call  
    printf("I am main line!");  
}
```

```
void abc() //function definition  
{  
    Printf("I am function body \n");  
}
```

#include<stdio.h>

FUNCTION SYNTAX

void abc(); *//function prototype declaration*

void main()

{

abc(); *//function call*

printf("I am main line!");

}

void abc() *//function definition*

{

Print("I am function body \n");

}

FUNCTION FOR ADDITION

```
#include<stdio.h>
```

```
#include<conio.h>
```

```
add(); //declaration
```

```
void main()  
{  
clrscr();  
add(); //calling  
getch();  
}
```

```
add() //definition  
{  
int a,b,c;  
printf("Enter two no. to add");  
scanf("%d%d",&a,&b);  
c=a+b;  
printf("%d",c);  
}
```

Benefits of function

- Modularization
- Easy to read
- Easy to debug
- Easy to modify
- Avoids rewriting of same code over and over
- Better memory utilization

FUNCTION FOR ADDITION

```
#include<stdio.h>
```

```
#include<conio.h>
```

```
add();
```

```
sub();
```

```
mul();
```

```
div();
```

```
void main()
```

```
{
```

```
clrscr();
```

```
add();
```

```
sub();
```

```
mul();
```

```
div();
```

```
getch();
```

```
}
```

```
add()
```

```
{
```

```
int a,b,c;
```

```
printf("Enter two no. for Addition");
```

```
scanf("%d%d",&a,&b);
```

```
c=a+b;
```

```
printf("Addition is : %d",c);
```

```
}
```

sub()

```
{  
int a,b,c;  
printf("Enter two no. for Substraction");  
scanf("%d%d",&a,&b);  
c=a-b;  
printf("Substraction is : %d",c); }
```

mul()

```
{  
int a,b,c;  
printf("Enter two no for Multiplication");  
scanf("%d%d",&a,&b);  
c=a*b;  
printf("Multiplication is : %d",c); }
```

div()

```
{  
int a,b,c;  
printf("Enter Two no for Division");  
scanf("%d%d",&a,&b);  
c=a/b;  
printf("division is : %d",c);  
}
```

Remember

- Program must have at least one function
- Function names must be unique
- Function is an operation, once defined can be used many times.
- One function in the program must be main
- Function consumes memory only when it is invoked and released from RAM as soon as it finishes its job.

FUNCTION CALL

Passing value between functions

- We can communicate between the calling and the called functions by passing the parameters.

There are two ways to pass parameters to a function:

- 1. CALL BY VALUE:**
- 2. CALL BY REFERENCE:**

Passing value between functions

CALL BY VALUE:

- You actually pass a copy of the variable to the function modifies the copy the original remains unaltered.

CALL BY REFERENCE:

- Call by reference mechanism is used when you want functions to do the changes in called parameters and reflect those changes back to the calling function .
- In this case addresses (pointer) of the variable are passed to function so that function can work directly over the addresses.

CALL BY VALUE

Example - Call by Value

```
#include<stdio.h>
```

```
#include<conio.h>
```

```
int square(int x);
```

```
void main() //main function
```

```
{
```

```
int a,b;
```

```
clrscr();
```

```
printf("enter any value:\n");
```

```
scanf("%d",&a);
```

```
b=square(a); //calling by value
```

```
printf("square is %d ",b);
```

```
getch(); }
```

```
int square(int x)
```

```
{
```

```
int y;
```

```
y=x*x;
```

```
return(y);
```

```
}
```

PASSING ARGUMENTS TO FUNCTION

How to Pass arguments to a function ?

```
#include <stdio.h>

int addNumbers(int a, int b);

int main()
{
    ... ..

    sum = addNumbers(n1, n2);
    ... ..
}

int addNumbers(int a, int b)
{
    ... ..
    ... ..
}
```

The diagram illustrates the flow of arguments. Two arrows originate from the parameters `n1` and `n2` in the function call `addNumbers(n1, n2);` within the `main` function. One arrow points diagonally down and to the left to the parameter `a` in the function definition `int addNumbers(int a, int b)`. The other arrow points diagonally down and to the right to the parameter `b` in the same function definition.

Example: User-defined function

```
#include <stdio.h>

int addNumbers(int a, int b); //function prototype

void main()
{
    int n1,n2,sum;
    printf("Enters two numbers: ");
    scanf("%d %d",&n1,&n2);
    sum = addNumbers(n1, n2); //function call
    printf("sum = %d",sum);
    getch();
}
```

Example: User-defined function

```
int addNumbers(int a, int b)//function definition
{
int result;
result = a+b;
return result; // return statement
}
```

RETURN STATEMENT IN FUNCTION

Return statement of a function

```
#include <stdio.h>
```

```
int addNumbers(int a, int b);
```

```
int main()
```

```
{
```

```
    ... ..
```

```
    sum = addNumbers(n1, n2);
```

```
    ... ..
```

```
}
```

```
int addNumbers(int a, int b)
```

```
{
```

```
    ... ..
```

```
    return result;
```

```
}
```

sum = result

The diagram consists of two L-shaped lines. The first L-shaped line starts from the 'return result;' statement in the addNumbers function, goes right and then up to an arrowhead pointing at the 'sum = addNumbers(n1, n2);' statement in the main function. The second L-shaped line starts from the 'return result;' statement, goes right and then up to an arrowhead pointing at the 'sum = result' text on the right side of the slide.

Example - Call by Value

```
#include <stdio.h>
```

```
void swap(int p1,int p2);
```

```
void main() //main function
```

```
{
```

```
int a=10, b=20;
```

```
printf("before swaping value of a=%d and b=%d\n",a,b);
```

```
swap(a,b); //calling by value
```

```
printf("\n\n values of a=%d and b=%d\n",a,b);
```

```
getch();
```

```
}
```

Example - Call by Value

```
void swap(int p1, int p2) //function method
{
    int c;
    c =p1;
    p1=p2;
    p2=c;
    printf("\n after swapping value of a(p1)=%d and b(p2)=%d\n",p1,p2);
}
```

CALL BY REFERENCE

Example - Call by Reference

```
void swap(int *p1,int *p2);
```

```
void main() //main function
```

```
{
```

```
int a=10;
```

```
int b=20;
```

```
printf("\n before value of a:%d and value of b:%d\n",a,b);
```

```
swap(&a,&b); //calling by reference
```

```
printf("\n value of a(p1):%d and value of b(p2):%d \n",a,b);
```

```
getch();
```

```
}
```

Example - Call by Reference

```
void swap(int *p1,int *p2) //function/method  
{  
int c;  
c = *p1;  
*p1 = *p2;  
*p2 = c;  
printf("after swaping value of a(p1):%d and value of  
    b(p2):%d\n",*p1,*p2);  
}
```

C Recursion

- A function that calls itself is known as a recursive function. And, this technique is known as recursion.
- The recursion continues until some condition is met to prevent it.
- To prevent infinite recursion, if...else statement (or similar approach) can be used where one branch makes the recursive call, and other doesn't.

How does Recursion work ?

```
void recurse()
{
    ... ..
    recurse();
    ... ..
}

int main()
{
    ... ..
    recurse();
    ... ..
}
```

The diagram illustrates the flow of recursive calls. A box labeled "recursive call" contains two arrows. One arrow originates from the `recurse();` line within the `recurse()` function and points back to the start of the `recurse()` function. The second arrow originates from the `recurse();` line within the `main()` function and points to the start of the `recurse()` function.

Factorial

```
#include <stdio.h>

factorial(int i)
{
    if(i <= 1)
    {
        return 1;
    }

    return i * factorial(i--);
}
```

```
void main()
{
    int i = 5;
    printf("Factorial of %d is %d\n", i,
    factorial(i));
    getch();
}
```

use loops instead of recursion. recursion is usually much slower.

Feature of recursion:

- *there should be at least one if statement used to Terminate recursion.*

It does not contain any looping statement.

Advantage of recursion:

- *It is easy to use*
- *It represent compact programming structures.*
- *It can be applied to calculate factorial of a a ,*
- *Fibonacci series.*

Disadvantage of recursion:

- *It is slower than that of looping statement because each time function is called.*

GETC() & PUTC() FUNCTION

Getc() & putc() function

```
#include<stdio.h>

void main ()
{
    char c;
    printf("Enter character: ");
    c = getc(stdin);
    printf("Character entered: ");
    putc(c, stdout);
    getch();
}
```

Getc() & putc() function

```
#include<stdio.h>
#include<conio.h>
void main()
{
char a[]="hello";
clrscr();
int i= 0;
while(a[i])
putc(a[i++],stdout);
getch();
}
```

THANKS
